1 Set up the environment

This section establishes the computational environment for processing socioeconomic data inputs for the Lower Savannah Council of Governments regional travel demand model using both R and Python platforms.

1.1 Install and load packages

The package installation process incorporates essential libraries for comprehensive geospatial data analysis.

The R environment includes {tidyverse} for data manipulation, {sf} for spatial data handling, {tidycensus} for Census Bureau data access, and {lehdr} for Longitudinal Employer-Household Dynamics data retrieval.

The Python environment focuses on core data science libraries including {pandas} for data manipulation, {geopandas} for spatial analysis, and {pygris} for Census data queries. These packages form the analytical backbone for processing demographic, employment, and geographic data required for travel demand modeling.

1.1.-.a R

```
# # Install required packages
# install.packages(c(
# "tidyverse",
#
   "vroom",
# "sf",
# "tidycensus",
# "lehdr",
# "arcgislayers",
  "mapview",
# "RColorBrewer",
# "janitor"
# ), dependencies = TRUE)
# Load packages
library(tidyverse) # Data manipulation and visualization
library(vroom)  # Read rectangular data
library(sf)  # Spatial analysis
library(tidycensus) # Accessing US Census Data
library(lehdr) # Access LODES data
```

```
library(arcgislayers) # ArcGIS REST API access
library(mapview) # Interactive mapping
library(RColorBrewer) # Color palettes for maps
library(janitor) # Data cleaning and preparation
```

1.1.-.b Python

```
# Install required packages if not available
# pip install numpy pandas geopandas shapely folium requests pygris
# Load processing libraries & modules
import os
from pathlib import Path
import zipfile
import requests
import urllib.parse
import warnings
warnings.filterwarnings('ignore')
# Load data and visualization libraries & modules
import numpy as np
import pandas as pd
import geopandas as gpd
import folium
from shapely.geometry import Point
# Census data query libraries & modules
from pygris import blocks, block_groups
from pygris.helpers import validate state, validate county
from pygris.data import get_census, get_lodes
```

1.2 Set global options and parameters

Configuration settings optimize performance and establish spatial consistency. The {tigris} cache prevents redundant TIGER/Line shapefile downloads. The South Carolina State Plane coordinate system (EPSG:3361) serves as the standard projection for accurate GIS operations

1.2.-.a R

```
# Set options
options(tigris_use_cache = TRUE) # cache tiger/line shapefile for future use
# set project CRS
project_crs <- "EPSG:3361"</pre>
```

1.2.-.b Python

```
# Set project CRS
project_crs = "EPSG:3361"
```

1.3 Set census API key

API authentication enables access to detailed demographic and economic datasets from the Census Bureau. The key configuration supports both R and Python environments for automated data retrieval workflows.

Need a Census API key? Get one for free at census.gov/developers

1.3.-.a R

```
# Set your API key into environment
tidycensus::census api key("your api key here", install = TRUE)
```

1.3.-.b Python

```
# Set your API key into environment
os.environ['CENSUS_API_KEY'] = 'your_api_key_here'
```

1.4 Project folder

The centralized directory structure organizes input data, processing files, and model outputs. The standardized root folder path ensures consistent file management across computing environments and team members.

1.4.-.a R

```
# Set your main data folder
root <- "M:/MA Project/SC LSCOG LRTP"</pre>
```

1.4.-.b Python

```
# Set your main data folder
root = "M:/MA_Project/SC_LSCOG LRTP"
```

2 Define study area

This section defines the geographic extent of the Lower Savannah Council of Governments region and loads the Traffic Analysis Zone (TAZ) geometry for spatial analysis.

2.1 Define state and counties

The study area encompasses six counties within South Carolina: Aiken, Allendale, Bamberg, Barnwell, Calhoun, and Orangeburg. These counties constitute the LSCOG planning region for travel demand modeling purposes.

2.1.-.a R

```
# Define state abbreviation and county names
state_abb <- "SC"
county_names <- c(
   "Aiken",
   "Allendale",
   "Bamberg",
   "Barnwell",
   "Calhoun",
   "Orangeburg"
)</pre>
```

2.1.-.b Python

```
# Define state abbreviation and county names
state_abb = "SC"
county_names = [
    "Aiken",
    "Allendale",
    "Bamberg",
    "Barnwell",
    "Calhoun",
    "Orangeburg"
]
```

FIPS code conversion translates state abbreviations and county names into standardized Federal Information Processing Standard codes. These codes enable consistent data retrieval across census datasets and ensure proper geographic matching with demographic and economic data sources.

2.1.-.c R

```
# Converting state abbreviation code to FIPS code
state_fips <- tidycensus:::validate_state(state = state_abb)
county_fips <- vapply(
    county_names,
    function(x) tidycensus:::validate_county(state = state_abb, county = x),
    character(1)
)
# Converting County Names to FIPS code
fips_codes <- paste(state_fips, county_fips, sep = "")
fips_codes</pre>
```

```
[1] "45003" "45005" "45009" "45011" "45017" "45075"
```

2.1.-.d Python

```
# Converting state abbreviation code to FIPS code
state_fips = validate_state(state_abb)
```

```
Using FIPS code '45' for input 'SC'
```

```
# Converting County Names to FIPS code
county_fips = [
   validate_county(state_fips, county)
   for county in county_names
]
```

```
Using FIPS code '003' for input 'Aiken'
Using FIPS code '005' for input 'Allendale'
Using FIPS code '009' for input 'Bamberg'
Using FIPS code '011' for input 'Barnwell'
Using FIPS code '017' for input 'Calhoun'
Using FIPS code '075' for input 'Orangeburg'
```

```
# Converting County Names to FIPS code
fips_codes = [f"{state_fips}{county}" for county in county_fips]
fips_codes
```

```
['45003', '45005', '45009', '45011', '45017', '45075']
```

2.2 Load TAZ geometry

The TAZ shapefile provides the fundamental spatial framework for travel demand modeling. The geometry is loaded from the TDM exports geodatabase and filtered to include only zones within the six-county study area using FIPS code matching.

Coordinate transformation converts the TAZ geometry to the project's standard coordinate reference system (EPSG:3361) for accurate spatial calculations. The attribute selection retains essential fields including TAZ identifiers, area measurements, area type classifications, and county assignments.

2.2.-.a R

```
)
) |>
sf::st_transform(project_crs) |>
dplyr::select(
   ID,
   Area,
   Acres,
   TAZ_ID = TAZ_IDs,
   AREA_TYPE,
   COUNTY,
   COUNTYID = countyID
)

```

3 Fetch raw data

This section retrieves demographic, economic, and employment data from multiple Census Bureau sources at the appropriate geographic scales for travel demand modeling.

3.1 2020 Decennial census

The 2020 Decennial Census provides population and housing data at the census block level, offering the finest spatial resolution for demographic analysis. Population variables include total population, group quarters population, and household population derived by subtraction. Housing variables encompass total dwelling units and household counts by size categories.

Household size distributions are consolidated into four categories: 1-person, 2-person, 3-person, and 4-or-more-person households. The 4-or-more category aggregates larger household sizes to simplify model implementation while maintaining essential demographic stratification for trip generation analysis.

For more information on the Decennial Census data, refer to the Decennial Census Technical Documentation.

3.1.-.a R

```
# Define variables to download
dec variables <- c(</pre>
   TOTPOP = "P1 001N", # Total Population
    GQPOP = "P18 001N", # Population living in Group Quarters

3.2 2020 ACS estimates

The American Community Survey 5-year estimates provide household income data at the block group level. Income categories are aggregated into three broad ranges: under \$15,000, \$15,000-\$49,999, and \$50,000 and above. This stratification aligns with travel behavior research indicating distinct mobility patterns across income levels.

The block group geography represents the finest spatial resolution available for ACS income data, providing sufficient detail for socioeconomic modeling while maintaining statistical reliability through the 5-year aggregation period.

For more information on the ACS data, refer to the ACS Technical Documentation.

3.3 2019 LEHD data

The Longitudinal Employer-Household Dynamics Workplace Area Characteristics data provides employment counts by industry sector at the census block level. Employment categories follow the North American Industry Classification System and are aggregated into transportation-relevant sectors including retail, services, manufacturing, and public administration.

The 2019 reference year represents pre-pandemic employment patterns, providing a stable baseline for long-term transportation planning. Employment data at the block level enables precise spatial allocation of work destinations within the travel demand model framework.

For more information on the LEHD data, refer to the LODES Technical Documentation.

3.4 2020 NCES school and college enrollment data

The National Center for Education Statistics provides comprehensive educational institution data including enrollment and staffing information for transportation planning analysis.

Public schools

Public school data is made available by National Center for Education Statistics through their Common Core of Data (CCD) program. For ease of processing, we retrieve the CCD from the ArcGIS REST service for the 2019-2020 academic year. The dataset includes total student enrollment and full-time equivalent teacher counts for each institution within the six-county region. Public schools represent major trip generation sources for both student and employee travel, requiring precise spatial location data for accurate modeling.

For more information on the NCES Public School data, refer to CCD Online Documentation.

To retrieve the data from ArcGIS REST service, we use the {arcgislayers} package in R and create a custom function in Python to read the ArcGIS FeatureLayer or Table. This has been implemented to function similarly to the {arcgislayers} package in R, allowing us to query the service with a SQL WHERE clause and return the data as a GeoDataFrame.

3.4.-.a R

```
# Public School Location data 2019-2020

Private schools

Private school enrollment data is accessed from the NCES Private School Universe Survey (PSS) archived dataset. The data is spatially enabled using latitude and longitude coordinates and filtered to include only institutions within the study area TAZ boundaries. Private schools contribute to the regional education trip matrix and must be incorporated alongside public institutions for comprehensive coverage.

For more information on the NCES Private Schools data, refer to PSS Online Documentation.

Post-secondary institutions

Post-secondary institution locations are obtained from the NCES Integrated Postsecondary Education Data System (IPEDS), filtered by state and county FIPS codes. These institutions generate significant travel demand through student commuting, employee travel, and visitor trips, making them essential components of the regional transportation network analysis.

For more information on the NCES Post-Secondary Education data, refer to IPEDS Documentation.

4 Clean data

The data cleaning process involves harmonizing multiple Census data sources to create a comprehensive socioeconomic dataset at the census block level. This requires careful interpolation and integration of American Community Survey (ACS) estimates with Decennial Census counts to maintain spatial consistency and statistical accuracy.

4.1 Household-weighted interpolation

The interpolation process transfers ACS block group data to individual census blocks using household counts as weights. This method ensures that socioeconomic characteristics are distributed proportionally based on residential density rather than simple geometric overlay. The {tidycensus} package provides robust interpolation functionality that preserves the extensive nature of count variables while maintaining spatial relationships. For Python, the interpolate_pw() function is implemented to achieve similar functionality using population-weighted interpolation.

4.1.-.a R

```
# Interpolate ACS data to Decennial Census blocks
lscog_acs_cb <- tidycensus::interpolate_pw(
  from = lscog_acs,
  to = lscog_dec,
  to_id = "GEOID",
  extensive = TRUE,
  weights = lscog_dec,
  crs = project_crs,
  weight_column = "HH"
)</pre>

```
Target geometries to interpolate data to
    weights_gdf : GeoDataFrame
       Weight geometries (e.g., census blocks) used for interpolation.
        If polygons, will be converted to points. Can be the same as to gdf.
    to id : str, optional
        Column name for unique identifier in target geometries.
        If None, creates an 'id' column.
    extensive : bool, default True
        If True, return weighted sums (for counts).
        If False, return weighted means (for rates/percentages).
    weight_column : str, optional
        Column name in weights gdf for weighting (e.g., 'POP', 'HH').
        If None, all weights are equal.
    weight placement : str, default 'surface'
       How to convert polygons to points: 'surface' or 'centroid'
    crs: str or CRS object, optional
        Coordinate reference system to project all datasets to
    Returns:
    GeoDataFrame
       Target geometries with interpolated numeric values

    lscog_acs.explore(column="INC_49999", color="red", legend=True,
tiles="CartoDB positron")
```

4.2 Combine population and households

The integration step merges the interpolated ACS socioeconomic data with the Decennial Census population and household counts. This join operation creates a unified dataset containing both demographic totals and detailed characteristics at the census block level. The left join ensures that all census blocks retain their geographic boundaries while incorporating available socioeconomic attributes.

4.2.-.a R

```

Income category adjustments reconcile the interpolated ACS estimates with actual household counts from the Decennial Census. The proportional allocation method redistributes income categories based on the ratio of interpolated totals to observed household counts, maintaining consistency between data sources. The three-tier income classification (under \$15,000, \$15,000-\$49,999, and \$50,000 and above) provides sufficient granularity for travel demand modeling while ensuring statistical reliability.

4.3 Employment data

The employment integration incorporates LEHD (Longitudinal Employer-Household Dynamics) workplace area characteristics into the combined dataset. This addition provides employment counts by census block, enabling the development of trip attraction models and work-based travel pattern analysis. The merge operation maintains the geographic integrity of census blocks while adding employment variables essential for comprehensive transportation planning.

5 Export raw data

The data export process creates standardized datasets for travel demand model development, maintaining both tabular and spatial formats to support various modeling applications. All exports follow consistent file naming conventions and directory structures to facilitate model integration and data management workflows.

5.1 TAZ data

The Traffic Analysis Zone (TAZ) boundary export provides the fundamental geographic framework for the regional travel demand model. The blank TAZ file serves as a template for subsequent socioeconomic data allocation, containing only zone identification fields and geometric boundaries without attribute data.

Export as CSV flat file

5.1.-.a R

```
# Export as CSV
lscog_taz |>
    sf::st_drop_geometry() |>
    readr::write_csv(
        file.path(
            root,
            "Task 1 TDM Development/Base Year/_raw/lscog_taz_blank.csv"
    ),
    append = FALSE
)
```

5.1.-.b Python

```
# Export as CSV
lscog_taz.to_csv(
    Path(root) / "Task 1 TDM Development" / "Base Year" / "_raw" /
"lscog_taz_blank.csv",
    index=False
)
```

Export as Geodatabase layer

5.1.-.c R

```
# Export as GDB
lscog_taz |>
    sf::write_sf(
        file.path(
            root,
            "Task 1 TDM Development/Base Year/_gis/LSCOG_2020Base_SE.gdb"
    ),
    layer = "lscog_taz_blank",
    append = FALSE
)
```

5.1.-.d Python

```
# Export as GDB
lscog_taz.to_file(
    Path(root) / "Task 1 TDM Development" / "Base Year" / "_gis" /
"LSCOG_2020Base_SE.gdb",
    layer='lscog_taz_blank',
    driver='FileGDB'
)
```

5.2 Census blocks to TAZ conversion

The block-to-TAZ conversion table establishes the critical linkage between fine-scale Census geography and the modeling zone system. This crosswalk file enables the aggregation of block-level socioeconomic data to TAZ boundaries while maintaining traceability to source geographies.

Export as CSV flat file

5.2.-.a R

```
# Export as CSV
lscog_cb |>
    sf::st_join(lscog_taz) |>
    dplyr::select(GE0ID20, ID, TAZ_ID) |>
    sf::st_drop_geometry() |>
    readr::write_csv(
    file.path(
        root,
        "Task 1 TDM Development/Base Year/_raw/lscog_block_taz.csv"
    ),
    append = FALSE
)
```

5.2.-.b Python

```
# Export as CSV
lscog_cb.merge(lscog_taz[['ID', 'TAZ_ID']], left_on='GEOID20', right_on='ID')
[['GEOID20', 'ID', 'TAZ_ID']].to_csv(
    Path(root) / "Task 1 TDM Development" / "Base Year" / "_raw" /
"lscog_block_taz.csv",
    index=False
)
```

5.3 Decennial census data at census block level

The decennial census block export captures the foundational demographic counts used throughout the modeling process. This dataset provides the most reliable population and household totals at the finest geographic resolution, serving as the base for all subsequent data integration and validation steps.

Export as CSV flat file

5.3.-.a R

```
# Export as CSV
lscog_dec |>
    sf::st_drop_geometry() |>
    readr::write_csv(
    file.path(
        root,
        "Task 1 TDM Development/Base Year/_raw/lscog_dec_block.csv"
    ),
    append = FALSE
)
```

5.3.-.b Python

```
# Export as CSV
lscog_dec.to_csv(
    Path(root) / "Task 1 TDM Development" / "Base Year" / "_raw" /
"lscog_dec_block.csv",
    index=False
)
```

Export as Geodatabase layer

5.3.-.c R

```
# Export as GDB
lscog_dec |>
    sf::write_sf(
    file.path(
        root,
```

```
"Task 1 TDM Development/Base Year/_gis/LSCOG_2020Base_SE.gdb"
),
layer = "lscog_dec_block",
append = FALSE
)
```

5.3.-.d Python

```
# Export as GDB
lscog_dec.to_file(
    Path(root) / "Task 1 TDM Development" / "Base Year" / "_gis" /
"LSCOG_2020Base_SE.gdb",
    layer='lscog_dec_block',
    driver='FileGDB'
)
```

5.4 ACS estimates at census block level

The interpolated ACS data export delivers income distribution estimates at the census block level, providing the socioeconomic stratification necessary for trip generation modeling. This processed dataset represents the final product of the household-weighted interpolation methodology, ready for direct integration into the travel demand model framework.

Export as CSV flat file

5.4.-.a R

```
# Export as CSV
lscog_acs_cb |>
  dplyr::select(GEOID, INC_14999, INC_49999, INC_50000) |>
  sf::st_drop_geometry() |>
  readr::write_csv(
    file.path(
      root,
      "Task 1 TDM Development/Base Year/_raw/lscog_acs_block.csv"
    ),
    append = FALSE
)
```

5.4.-.b Python

```
# Export as CSV
lscog_acs_cb[['GEOID', 'INC_14999', 'INC_49999', 'INC_50000']].to_csv(
    Path(root) / "Task 1 TDM Development" / "Base Year" / "_raw" /
"lscog_acs_block.csv",
    index=False
)
```

Export as Geodatabase layer

5.4.-.c R

```
# Export as GDB
lscog_acs_cb |>
  dplyr::select(GE0ID, INC_14999, INC_49999, INC_50000) |>
  sf::write_sf(
    file.path(
      root,
      "Task 1 TDM Development/Base Year/_gis/LSCOG_2020Base_SE.gdb"
    ),
    layer = "lscog_acs_block",
    append = FALSE
)
```

5.4.-.d Python

```
# Export as GDB

)
```

5.5 LEHD data at census block level

The employment data export provides comprehensive workplace characteristics by industry sector at the census block level. This dataset captures the spatial distribution of employment opportunities across the study region, supporting both trip attraction modeling and economic impact analysis.

Export as CSV flat file

    layer = "lscog_emp_block",
    append = FALSE
)
```

5.5.-.d Python

5.6 Public schools to TAZ

The public school location export integrates educational facility data with the TAZ system, providing essential inputs for school-related trip modeling. Student and teacher counts by facility support the development of specialized trip generation rates for educational purposes.

Export as CSV flat file

5.6.-.a R

```
# Export as CSV

    layer='lscog_pubsch_loc',
    driver='FileGDB'
)
```

5.7 Private schools to TAZ

The private school dataset complements the public education data by capturing enrollment patterns in private educational institutions. This comprehensive coverage of educational facilities ensures that all school-related travel demand is properly represented in the regional model.

Export as CSV flat file

5.7.-.a R

```
# Export as CSV

)
```

6 Aggregate data to TAZ

The aggregation process transforms fine-scale census block data into TAZ-level inputs suitable for travel demand modeling. This spatial aggregation preserves the total counts while organizing data according to the modeling zone structure required for trip generation and distribution analysis.

6.1 Population, households, and employment

The spatial join operation aggregates all demographic, housing, and employment variables from census blocks to their corresponding TAZs using centroid-based assignment. This process ensures that each block's socioeconomic characteristics are properly allocated to the appropriate modeling zone while maintaining data integrity through comprehensive summation of all relevant variables.

6.1.-.a R

```
# Aggregate population, households, and employment to TAZ
lscog_taz_pop <- lscog_taz |>
    sf::st_join(
        lscog_pop_hh_emp |> sf::st_centroid(of_largest_polygon = TRUE)
) |>

7 Combine into a single data

This step integrates all TAZ-level socioeconomic datasets into a comprehensive base year file for travel demand modeling. This consolidated dataset contains all essential variables organized in a standardized format with geographic identifiers, demographic characteristics, employment data, and educational enrollment totals for each traffic analysis zone in the study region.

8 Data checks and validation

The validation process ensures data integrity and consistency across all socioeconomic variables through systematic checks of categorical totals. These validation steps identify any discrepancies between aggregate totals and component categories that may have occurred during the interpolation or aggregation processes.

8.1 Household size total

This validation confirms that the total household count matches the sum of all household size categories for each TAZ. Any discrepancies indicate potential issues in the household size distribution that require investigation and correction before model implementation.

8.1.-.a R

```
# check the sum of household by household size
lscog_se_base |>
  dplyr::filter(HH != (HH_1 + HH_2 + HH_3 + HH_4)) |>
  nrow()
```

```
[1] 0
```

8.1.-.b Python

```
0
```

8.2 Household income total

The income category validation verifies that household totals equal the sum of all three income brackets across all zones. This check ensures the integrity of the income distribution data following the proportional allocation methodology applied during the ACS interpolation process.

8.2.-.a R

```
# check the sum of household by income level
lscog_se_base |>
dplyr::filter(HH != (INC_14999 + INC_49999 + INC_50000)) |>
nrow()
```

```
[1] 0
```

8.2.-.b Python

```
# check the sum of household by income level
lscog_se_base[
   lscog_se_base['HH'] != (lscog_se_base['INC_14999'] +
lscog_se_base['INC_49999'] +
```

```
lscog_se_base['INC_50000'])
].shape[0]
```

```
0
```

8.3 Employment categories

The employment validation confirms that total employment equals the sum of all industry sector categories for each TAZ. This comprehensive check validates the LEHD data integration and ensures that no employment is lost or double-counted during the sectoral disaggregation process.RetryClaude can make mistakes. Please double-check responses.

8.3.-.a R

```
# check the sum of employment by categories
lscog_se_base |>
  dplyr::filter(
   TOTAL_EMP !=
      (AGR FOR FI +
        MINING +
        CONSTRUCTI +
        MANUFACTUR +
        TRANSP_COM +
        WHOLESALE +
        RETAIL +
        FIRE +
        SERVICES +
        PUBLIC ADM)
  ) |>
 nrow()
```

```
[1] 0
```

8.3.-.b Python

```
# check the sum of employment by categories
lscog_se_base['TOTAL_EMP'] != (
    lscog_se_base['AGR_FOR_FI'] +
    lscog_se_base['MINING'] +
    lscog_se_base['CONSTRUCTI'] +
    lscog_se_base['MANUFACTUR'] +
    lscog_se_base['TRANSP_COM'] +
    lscog_se_base['WHOLESALE'] +
    lscog_se_base['RETAIL'] +
    lscog_se_base['FIRE'] +
```

```
lscog_se_base['SERVICES'] +
    lscog_se_base['PUBLIC_ADM']
)
].shape[0]
```

```
Θ
```

9 Export the final data

The final export creates the complete TAZ-level socioeconomic dataset in both tabular and spatial formats for direct integration into the travel demand model. This comprehensive dataset serves as the primary input for trip generation, providing all necessary demographic, economic, and educational variables organized by traffic analysis zone for the LSCOG regional modeling system.
